# PHASE I BOOK EXPLOITATION

POL/4904

- Z zagadnień techniki wojennej: Broń termojądrowa, BSP, automatyka, radiolokacja, telewizja, podczerwień, pociski rakietowe, hydroakustyka
  (Problems in Military Technology: Thermonuclear Weapons, Radiation
  Warfare (BSP), Automation, Radar, Television, Infrared, Rocket Miswarfare (BSP), Automation, Radar, Television, Infrared, Rocket Missiles, Hydroaccoustics) Warsaw, Wydawn. Ministerstwa Obrony Narodowej,
  1959. 370 p. Errata slip inserted. 3,000 copies printed. (Series:
  Biblioteka wiedzy wojskowej. Seria II)
- Scientific Ed.: Henryk Sejneński; Ed.: Michał Wróblewski; Tech. Ed.: Kazimierz Szubert.
- PURPOSE: This book is intended for the general reader interested in modern weapon developments.
- COVERAGE: The book contains ll articles in which the various types of modern weapon systems are discussed. The information is based on Western sources. The basic principles of atomic reactions are given and atomic explosions are described citing as examples the Hiroshima and Nagasaki bombs. Theory concerning radiation substances and the effects of radiation on living

card 1/4

Problems in Military (Cont.)

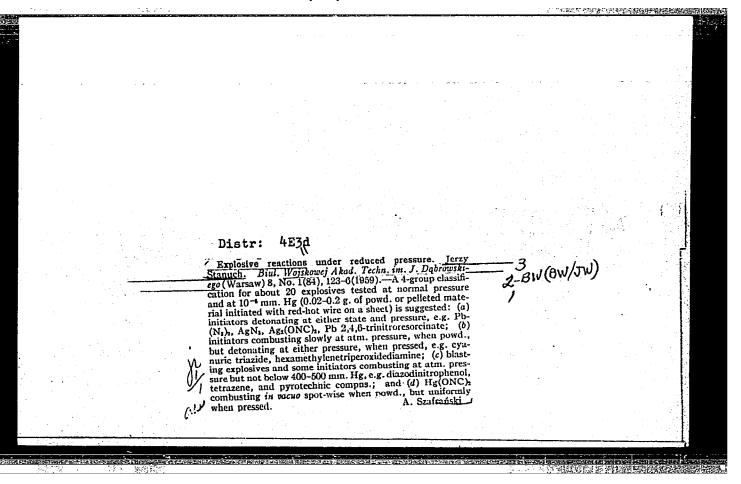

POL/4904

organisms are explained. Automation in artillery, aviation, and radar are described and some information on computers is included. Fundamentals of radar systems are given and basic radar equipment is described. The book also covers ground installations and equipment for aircraft guidance, ground installations for artillery fire control, installations on aircraft and naval installations. The principles of television are explained and possible uses of television in the armed forces are given. Infrared military equipment including telescopes, cameras, sights, thermopelengators, telephones, night vision apparatus, etc., are briefly described. Fundamentals of hydrolocation are given and propagation of sound waves in various media is described. The application of acoustics in the detection of fuses is pointed out. In the field of missiles the principle of their operation and a brief history of missile development are given. Mobile and stationary launchers are discussed and some information on rocket launching from aircraft and naval units is given. Remote control and self-guidance systems are briefly discussed, as are television guidance and antimissile defense. No personalities are mentioned. There are no references.

TITLE: On the Transition Process in Grid-Modulated Power Generators

PERIODICAL: Nachrichtentechnik, 1960, No. 6, pp. 261 - 265

TEXT: Literature (Refs. 1, 2 and 3) describes a transition process not only in the grid circuit of a low-frequency power amplifier, but also in the grid circuit of a grid-modulated power generator. The reason is the presence of a remarkable stray inductance of the transformer, which couples the initial and power stage of a low-frequency amplifier and the modulation and generator stage of grid-modulated generators (Fig. 1). Non-linear distortions and parasitic oscillations are thereby caused in the grid circuit of the generator. The equivalent circuit of the grid-modulated generator (Fig. 2) allows the examination of the stationary and non-stationary processes in these generators. The transition function is mathematically determined. To observe the transition process on an oscillograph, the test device (Fig. 9) was constructed. The course of the grid current and the input voltage of the generator, as observed on the oscillograph screen, are shown in Figure 10. There are 10 figures and 3 references: 2 Soviet and 1

AUTHOR:

Some Problems of Medium-wave Broadcast Antennas With a Cross Section Gradually Increasing Toward the Center (Fish-bellied

Antennas)

PERIODICAL:

Hochfrequenztechnik und Elektroakustik, 1960, Vol. 69, No. 5,

pp. 161 - 170

TEXT: The purpose of the present paper is to find the reason for the bad antifading properties of fish-bellied antennas. After introducing a sine function for the distribution of capacitance along the antenna, the author approximately calculates the basic equations of the double line for the case without damping, and therefrom he determines the distribution of current and voltage, as well as the (variable) wave impedance along the emitter, both for the half-wave antenna and its perpendicular radiation emitter, both for the half-wave antenna and its perpendicular radiation efield. The results obtained may be extended to antennas having a length of field. Using some results known from literature, the author gives a simple method of determining the vertical radiation fields of real fish-bellied

Card 1/2

Some Problems of Medium-wave Broadcast Antennas G/009/60/069/005/001/003 With a Cross Section Gradually Increasing B010/B063 Toward the Center (Fish-bellied Antennas)

antennas by taking damping into account. This method is based on the fact that, in the presence of damping, there is a second (active) current component on the antenna, which causes an additional field which may be easily calculated. The total field consists of the additional field and the undamped radiation field. It is found that the bad antifading properties of fish-bellied antennas fed at the foot, as, e.g., concerning the position of zero angles, is primarily due to the effect of damping. Thus, the author refutes the view of some authors who assumed that the unfavorable conditions of radiation are mainly due to the varying wave impedance, or to the deviation of current distribution from the sinusoidal form. Finally, the author gives some methods of improving the antifading properties among which the change of the feeding point or the installation of additional emitters are of particular significance. There are 10 figures, 1 table, and 15 references: 2 Soviet, 3 US, and 10 German.

TITLE:

A simple electronic device for statistical investigations of

radio-wave propagation

PERIODICAL: Elektrosvyaz', no. 4, 1961, 28-34

TEXT: In the theory of radio-wave propagation, the ionospheric propagation plays an important part. On account of ionospheric conditions, the amplitude of the resultant field varies chaotically, in the point of reception, and fadings take place. These fluctuations of the field intensity (due to the continuously changing electron density of the ionosphere layers, to the variation of their altitude and to the interaction of waves propagating along many different ways) are represented quantitatively by a fortuitous along many different ways) are represented quantitatively by a fortuitous function of time E(t) or, rather, by one of the possible forms  $E_k(t)$  (k=1, 2, 3...) of this constantly changing function. The maxima and minima of the recorded graphs of  $E_k(t)$ , as well as certain statistical parameters, are generally used in practical estimates. Two of these parameters are the time-erally value E(t) constant component of the process) and the so-called median

Card 1/8

A simple electronic device for...

value  $E_0$  (the value of the field intensity exceeding its instantaneous values for 50% of the observation time). The function  $E_k(t)$  is considered as a stationary fortuitous function (i. e. the conditions provoking the process it represents do not vary with time). Therefore,

 $\overline{E} = \int_{-\infty}^{+\infty} x p(x) dx = \lim_{T \to \infty} \frac{1}{T} \int_{0}^{1} E_{k}(t) dt$  (1)

where  $\overline{E}$  is the average value of the stationary function  $E_k(t)$ , p(x) is the function of the probability density of the fortuitous stationary process, and  $\overline{T}$  is the duration of the observation. The determination of the average value of the field intensity can thus be reduced to the calculation of the integral of the second equation of (1). The electronic device described in the present article is based upon this method and allows to determine directly the average value of the field intensity. This electronic device (Fig. 2) consists mainly of a two-stage d-c amplifier with a relatively high input resistance, and of an electric d-c counter used as integrating apparatus. The basic diagram of the device is shown in Figure 3. Under the conditions of ionospheric propagation, the negative voltage at the output of the second detector (A) will vary from zero (minimum amplitude of the signal that reaches the

Card 2/8

20476 \$/106/61/000/004/004/004 A055/A133

A simple electronic device for ...

receiver) to a certain negative value (maximum magnitude of the signal). variations of the resultant field intensity picked up by the receiving antenna will thus manifest themselves, in the device, by proportional variations of the anode current of the second stage of the amplifier (from a certain minimum to a certain maximum value). On the other hand, the rotor of the counter (connected in series with the anode circuit of the second amplifier stage) will rotate in rhythm with the variations of the current flowing through its windings. At the end of the observation time, the number of revolutions registered by the counter will serve as a measure for the average value of the current through the counter, i.e. a measure for the average value of the field strength in the point of reception. Potentiometers P1, P2 and P3 are used respectively: 1) to obtain optimum compensation; 2) to vary the amplification of the signal applied to the second tube; 3) to fix the initial working point of the second tube. The power is supplied by the 220 volt mains through a ferro-resonance stabilizer and an ordinary full-wave rectifier. The maximum anode current of ... second stage being of the order of 10 to 100 ma, whereas the rated currer through the counter attains usually several amperes, it is appropriate to switch off the counter shunt-resistance; the anode current of the second tube will then pass direct through the windings of the

Card 3/8

A055/A133

A simple electronic device for ...

counter rotor. The electrical data of the counter being known, it is easy to establish the following equation for the current flowing through it:

 $I_{count.} = \frac{1000}{60} \frac{R_{sh}}{R_{sh}+r} \frac{k!}{U!} \frac{n}{T} = k \frac{n}{T}; \quad (k = \frac{1000}{60} \frac{R_{sh}}{R_{sh}+r} \frac{k!}{U!})$ where  $I_{count}$  is the rotor current,  $R_{sh}$  is the d-c shunt-resistance, r is the d-c resistance of the rotor windings, k' is the constant of the counter, U is the nominal counter voltage, n is the number of rotor revolutions, and T is the duration of the observation. If n and T are known, equation (2) allows to calculate the average value of the current I count. On the other hand, the receiver to which is connected the electronic device has been calibrated, so that  $E = \varphi_2(-U_{inp})$  is known (E being the field intensity in the point of reception). The average value of E (for the time that lasts the observation) can therefore be found as follows with the aid of the nomogram of Figure 8: starting from the calculated current I count = Io on the ordinate-axis I count; one has but to follow the arrows, and the average value  $(E_{\rm o})$  is finally found on the other ordinate-axis (axis E). To test the described electronic device, a series of observations was made, where an ordinary recording apparatus was also used. The results of these tests are grouped in a table that is repro-

AUTHOR: Stanyukovich, A. V.

TITLE: Study of the effect of stress concentrators on the deformation capacity of heat-resistant steels

SOURCE: AN SSSR: Institut metallurgii. Issledovaniya po zharoprochny\*m splavam, 

TOPIC TAGS: steel, heat resistant steel, steel deformation capacity, deformation capacity, stress dependence, stress concentrator

ABSTRACT: In order to determine to what degree the presence of minor surface defects may affect the performance of a material, comparative tests were made on smooth and notched samples. The notches were created by using the diamond cone of a Rockwell instrument to make 7 small depressions on the surface of the gage length of cylindrical samples (8 mm in diameter) of E1612 austenitic steel. The conical depressions were arranged along a spiral with a 15-mm pitch. An experimental check showed that under tension the strain is distributed uniformly over the entire gage length of samples with conical depressions. Tests were conducted in a temperature range of 500-800C with a strain rate of 0.6%/hour. In all cases, failure began at the bottom of the conical depressions, but at 500°C

ACCESSION NR: AT4013933

The variation of this sensitivity in terms of strain capacity as a function of temperature is also analyzed and a graph is plotted to represent this relation. The author also studied the influence on the strain capacity which may be exerted by certain internal defects, both those already present within the material and those which develop during its use. Special attention, in this regard, is directed at the role of primary intercrystalline fissures. The author considers as firmly established the following points:

1) in actuality, all materials are sensitive to concentrators at high temperatures, but the specific effect of the concentrators depends to a large degree on the properties of the material and the conditions of its use; 2) sensitivity to the concentrator increases noticeably in a zone of temperatures and strain rates at which the failure is usually intergranular;

3) the effect of concentrators on the performance of materials can be established through a study of the deformation capacity of the steel under the proper conditions. Orig. art. has:

Heat-resistant Materials for Power Machinery Building. (Zharoprochnyye materiyaly dlya energomashinostroyeniya) TITIE:

Energomashinostroyeniye, 1957, Vol.3, No.11, pp. 22 - 26

PERIODICAL: The article commences with a statement of the importance of studying mechanical properties of metals at high temperatures and with a review of early work on this subject in the USSR. ABSTRACT:

and with a review of early work on this subject in the USSK.

After the war, work developed extensively on the study of the properties of heat-resistant materials. New laboratories for this purpose were set up in the Central Scientific Research Institute of Engineering Technology (TsNIITMASh), the Central Scientific Research Institute for Ferrous Metallurgy (TsNIIChERMET) at the Neva Works imeni Lenin (NZL), the Kharkov Turbine Works (KhTZ) and elsewhere and the laboratories at the Central Boiler Turbine Institute (TsKTI) and the Leningrad Metal Works (IMZ) were extended. In the solution of metallurgical problems involved in the manufacture of new heat-resistant mterials, a leading part has been played by such enterprises as "Elektrostal",

Card 1/7 the Ural Engineering Works (Uralmashzavod), the Neva Works

114-11-5/10

Heat-resistant Materials for Power Machinery Building.

Turbine Institute and at Leningrad University resulted in the derivation of a relationship between the quantity of metal reacting with oxygen and the time. A great deal of work was done on the ageing of high alloy steel by study of the structure and properties of a group of steels after lengthy exposure to high It was shown that, for a number of materials, identical structures can be obtained at different ageing temperatures by altering the test time. For many materials, the structural condition can be related to the impact strength. This is very useful in maintenance work. Procedures have been developed for studying the fatigue strength at high temperatures.

Recently, more attention has been paid to physical methods of investigation, such as determination of thermal conductivity and

Experimental results on creep in pipes under pressure have temperature coefficient of expansion. been compared with results of the usual tension tests and a method has been developed for calculating the equivalent stress in pipes under pressure from the results of tests on ordinary specimens that is applicable to all boiler steels (see Fig. 5). The development of the first boilers and turbines for superhigh steam conditions provided a great stimulus to the investi-Card 3/7 gation of heat-resistant materials. Examples of heat-resistant

114-11-5/10

Heat-resistant Materials for Power Machinery Building.

tungsten, vanadium and niobium to a total content of 1-3%. These steels are used after heat treatment. Steels of this kind are 15x11m9, 15x12mm and 1x12mm Variants of cast-chromium heat-resistant steels are of considerable interest; materials of these kinds are steels XIINS and XIINA.

Since the war, investigational work and developments in metallurgical work on casting and forging have led to the development of a series of heat-resisting austenitic steels. One of the first of these which has been studied in the most detail is steel 3N-405 which has satisfactory technological properties and sufficiently high heat-resistance to combine with good structural stability. It has been used for the manufacture of blades and a number of other parts of turbines for super-high steam conditions and for gas turbines. During development work on the welded rotor for a gas turbine several large parts were made from this steel using different manufacturing procedures. The parts were subsequently tested at the Leningrad Metal Works and the Central Boiler Turbine Institute and it was found necessary to improve the quality of ingots and the technology of hot working. A good deal of work was done on the welding of this steel.

Steel 3M-572 has been manufactured and rolled by the "Elektro-Card5/7stal\* Works and investigated in detail by the Central Boiler

APPROVED FOR RELEASE: 08/25/2000 Machine RD PSG 065 3R001652910011-5"

sensitivity to the presence of cuts so that it is very suitable for the manufacture of studs and bolts intended to operate at temperatures of up to 580 °C, and also for large forgings for

Steel 94-612, a chrome-nickel austenitic steel alloyed with gas turbine discs and rotors. tungsten and titanium, has been developed. It has good mechanical properties in the temperature range 20 - 650 C. The impact strength is maintained at a high value after prolonged ageing at 650 - 700 °C.

A great deal of work has been done on the development and use of cast austenitic steel. One such steel is brand All which has high heat-resistance and stability so that it can be used at working temperatures of up to 650 C. Considerable difficulties had to be overcome in the manufacture of castings of heat-resistant austenitic steels because of their tendency to form films, which leads to the formation of wrious defects on the surface of the ingots. These defects are found in all existing austenitic heat-resistant steels. Reliable welds can be made of these steels only in regions from which such defects and porosity are completely absent. A good deal of work has been

AUTHORS: Stanyukovich, A.V. (Cand. Tech. Sc.), Zemzin, V.K. (Cand. Tech. Sc.)

TITLE: Long Duration Strength of Weld Joints at Elevated Temperatures.

(Dlitel'naya prochnost' svarnykh soyedineniy pri vysokikh
temperaturakh)

PERIODICAL: Metallovedeniye i Obrabotka Metallov, 1958, Nr 2, pp.12-18 (USSR)

ABSTRACT: The aim of the investigation described in this paper was to study the operation of weld joints under conditions of static loading at elevated temperatures, paying attention mainly to long duration strength in the case of simultaneous loading of various zones of the weld joint. The investigations were carried out on pearlitic 12MoX steel (0.13% C; 0.56% Cr; 0.27% Mo; 0.22% V), welded with pearlitic electrodes, using cutoffs of steam piping of 270 mm outer dia and a wall thickness of 32 mm and electrodes of 3 and 4 mm dia; after welding, the specimens were tempered at 740°C for 2 hours. Experiments were also carried out on the austenitic steel, 3M405 (0.09% C; 15.5% Cr; 14.4% Ni; 2.2% Mo; 1% Nb), welded with austenitic electrodes KTN5, and tempered for two hours at 740°C. In addition to the weld joints the specimens of the base material and of metal deposited from Card 1/4

129-2-3/11

Long Duration Strength of Weld Joints at Elevated Temperatures.

steel 12MQX produced by pearlitic electrodes had a strength equal to that of the base metal; the zone of the joint which is most stable against intercrystallite fracture is the thermally influenced zone. The weld joints or the austenitic steel, 3N405, produced by the austenitic electrodes KTN5, have a strength equal to that of the base metal: intercrystallite corrosion occurs primarily in the base metal. The long duration strength of various weld joints produced by austenitic electrodes on pearlitic steel is considerably higher than it is for pearlitic weld joints in the case of stresses acting in the direction of the weld axis: in this case fracture begins in the least plastic part of the joint, namely, in the austenitic weld. If the forces act transverse to the weld axis the fracture starts off near the fusion line in the zone with transient structures. In selecting electrodes for welding high temperature steel, it is necessary to consider the plastic properties of the weld under conditions of long duration stresses; for weld joints this property is decisive from the point of view of the forces acting in the direction of the weld axis. There are 3 tables, 4 figures and 3 Slavic references.

Method of Evaluating the Durability of Welded Joints (Metody TITLE:

otsenki dlitel'noy prochnosti svarnykh soyedineniy)

PERIODICAL: Zavodskaya Laboratoriya, 1959, Vol 25, Nr 6, pp 715 - 721 (USSR)

Durability (D) is one of the most important criteria for evaluating welded joints for continuous duty at high temperatures. ABSTRACT:

Therefore, it is of preeminent importance to devise the most rational method for the (D) determination. (D) was hitherto evaluated by testing cross welded samples (I). Service demands made on many welded structures in power engineering plants

(as, for example, welded joints in steam pipings, drum rotors, etc) in which the stress is along the welding seam, do not comply with conditions in the abovementioned tests; therefore,

a special method (II) of testing plane samples with longitudinal weldings (Fig 3) was devised at the Institute of the authors

of the present paper (see Association) (Ref 2). The fundamental characteristics of both these methods of (D) testing((I) and

(II)) are described and results obtained on typical welded Card 1/2

Method of Evaluating the Durability of Welded Joints

sov/32-25-6-25/53

joints are given. The fundamental rules governing the sample deformation according to (I) may be depicted by a certain scheme (Fig 4), by which it is possible to identify the least resistant component of the welded joint and the melting zone sensitivity as related to the stress concentration. Respective results are given and explained, that were obtained on weldings of weakly alloyed 12MFKh steel, 15Kh11MF chromium steel, EI415 and 15Kh1M1F perlite steels, and EI405 austenite steel (Table 1, Fig 5) as well as EI612K steel, weldings of various 12KhMF + 15Kh11MF and 12MFKh steels (with KTI-5 austenite electrodes or TSh-20 and Tsh-27 perlite electrodes) (Table 1, Fig 6) et alia. Tests (II) allow the determination of the common performance of individual zones of the welded joint; in this connection the applicability of the abovementioned deformation scheme (Fig 4), as well as the decisive role played by the plasticity of the individual welding joint components are confirmed. Respective testing results (Table 2, Fig 7) obtained on the abovementioned steel types and electrodes are given. There are 7 figures, 2 tables, and 6 Soviet references. TITLE:

Evaluation of the Plasticity Properties of Fireproof Steels

With Respect to Time

PERIODICAL:

Zavodskaya laboratoriya, 1959, Vol 25, Nr 9, pp 1101-1106 (USSR)

ABSTRACT:

The test method with a constant deformation speed (DS) can be used to evaluate the plasticity properties (PP) of fireproof steels (Karskiy, Ref 2). In the case under discussion, the tensile tests were made within the temperature range 400-800° at a temperature change of 50°. Several test series were made at constant (DS), the maximum (DS) being 180 or 313%/h and the

minimal (DS)  $1 \cdot 10^{-1}$  to  $2 \cdot 10^{-2} \% / h$ . The tests at maximum (DS) were made on usual tensile-testing machines, IM-4r and IM-12, and those at minimum (DS) on the specially constructed machine 5 IM (Fig 1) which is described. The tests were performed on the last-mentioned machine on the following fireproof steels: the pearlitic chrome-molybdenum-vanadium steel EI10, the austenitic steel 1Kh18N9T and EI612, as well as some nickel alloys with various additions. The results of measurement, which are explained in detail, led to the following conclusions:

Card 1/3

Evaluation of the Plasticity Properties of Fireproof Steels With Respect to Time

sov/32-25-9-30/53

variation in (PP) with temperature at constant (DS) is described in semilogarithmic coordinates by a V-shaped curve. Deceleration of (DS) shifts this curve to lower temperatures. A family of such V-shaped curves can show the change of minimum deformability (mD) of the steel in dependence on temperature. (mD) rises with temperature. The dependence of relative elongation on (DS) at constant temperature (up to minimum deformation) can be expressed by a step function. Having reached the level of minimum plasticity, a further deceleration of (DS) results in an increase of relative elongation. The decrease intensity of plasticity rises on destruction with a deceleration of (DS) with temperature up to a certain limit at which it falls again. At maximum test temperatures rising deformability can be observed. Temperature rise shifts the embrittlement interval to high (DS). The decrease of plasticity properties of steels at high temperatures is attributed to the development of intercrystalline

destruction. The deformability of fireproof steels can be approximately characterized by "plasticity diagrams", which were plotted by extrapolation of the test results. There are 5 figures and 4 references, 2 of which are Soviet.

TITLE:

Deformability of Certain Materials for High-Temper-

ature Service

PERIODICAL:

Energomashinostroyeniye, 1960, No. 5, pp. 26-30

TEXT: The object of the present investigation was to study the effect of temperature and rate of strain on the plasticity of several engineering alloys used in the construction of power generating plant. The materials studied included: (a) Steel 3Nio (EIIO), oil-quenched from 940°C and tempered for 2 h at 630°C; (b) an austenitic steel IXIBH9T (IKh18N9T), quenched from 1050°C and tempered for 3 h at 680°C; (c) an austenitic steel 3N6!2(EI612), quenched from 1150°C and tempered for 20 h at 750°C; (d) a titanium-bearing nickel/chromium alloy A ("A"); a similar alloy "\textsupercolor ("G") with a lower titanium content, but containing a small proportion of niobium; and (e) 2 nickel/chromium alloys 5" ("B") and "B" ("V") with a high content of titanium, tungsten, and molybdenum. (All the nickel-base alloys were tested after a heat treatment designed to give them the maximum high-temperature

The Effect of Work-Hardening on Deformability of Steel TITLE:

Metallovedeniye i termicheskaya obrabotka metallov, 1Kh18N9T 1960, No. 7, pp.7-14 + 1 plate PERIODICAL:

TEXT: Following the findings of Trank, Cuff, and Grant (Ref. 1), who had reported that plasticity of austenitic steels at high temperatures to considerably lemmas to considerably lemm tures is considerably lowered by preliminary deformation, the present author studied the effect of work-hardening on the hightemperature ductility of a steel, containing 0.12% C, 1.0% Mn, 16.98% Cr, 10.96% Ni, 0.01% S, 0.018% P, 0.66% Si, and 0.5% Ti.
The experimental work was carried out on tensile test pieces (8 mm diameter 10 mm gauge length) both in the best treated condition diameter, 40 mm gauge length) both in the heat-treated condition (quenched from 1050°C and tempered for 3 h at 680°C) and after the same heat treatment, followed by 18 and 34% cold deformation (in temperation) the former degree of deformation having been chosen as tension), the former degree of deformation having been chosen as that encountered in practice in bending tubes for steam power plant. Both elongation,  $\delta$ , and reduction of area,  $\psi$ ,

The Effect of Work-Hardening on Deformability of Steel 1Kh18N9T of various depth and nature (inter- and intra-crystalline) were formed on the test pieces. Correlation of the results of mechanical tests and metallographic examination indicated that although the surface cracks were formed already at high rates of strain, their effect on the ductility of steel became apparent only when intercrystalline fissures were formed in the interior of the test pieces, under which conditions the surface cracks changed into coarse, inter-crystalline cracks, causing the ultimate fracture of the test pieces. By extrapolating empirical curves (5 versus rate of strain) it was shown that in the case of the heat-treated material, & is never lower than 1%, whereas the heat-treated material subjected to 18% preliminary deformation, can be expected to fail with 5 attaining value as low as 0.3%. The variation of & with rising temperature is attributed by the present author to the transition from one mode of plastic deformation to another. It is postulated that minimum ductility of the investigated steel is attained at a certain critical temperature, below which deformation by slip

Card 3/4

The Effect of Work-Hardening on Deformability of Steel 1Kh18N9T predominates, the diffusion creep playing the predominant part above this temperature. This critical temperature becomes higher with increasing rate of strain and decreasing degree of preliminary deformation. There are 8 figures, 1 table and 3 references: 2
